Intelligent Laundry System: Project Report

1. Project Overview

The Problem Addressed

Traditional washing machines heavily rely on user guesswork. Users must manually determine the correct water temperature, spin speed, and detergent amount. Incorrect guesses frequently lead to fabric damage, color bleeding, or poor cleaning performance.

The Solution Developed

This project presents an **Intelligent Laundry System** that eliminates guesswork using artificial intelligence. The system operates in three simple, automated phases. First, it takes images of the laundry load. Second, the AI acts as the system's "Eyes" to figure out exactly what the clothing is made of (such as cotton or silk) and how dirty it is. Third, the AI acts as the system's "Brain" to calculate the mathematically perfect amount of water, detergent, and cycle temperature, ensuring safe and spotless laundry every time.

Real-World Business Impact

For anyone reviewing this project, the core value is simple: **We are turning dumb appliances into smart appliances.**

- **For Users**: It saves time, prevents ruined clothing, and guarantees perfectly clean laundry.
- **For the Environment**: By using AI to mathematically calculate the exact water and detergent needed based on the clothes' weight and soil level, the system drastically reduces water and chemical waste.

---

2. Software and Technology Stack

To achieve this automated intelligence, we built a robust and modern backend pipeline. The core technologies utilized in this project include:

- **Python (3.9+)**: The primary programming language utilized for all backend logic and API structuring.
- **FastAPI**: A high-performance web framework used to build both the image processing API and the parameter calculation API.
- **Uvicorn**: The ASGI web server used to host and test our FastAPI applications locally.
- **Google Generative AI (Gemini 1.5 Flash)**: The core artificial intelligence engine. We utilized this smart model to look at the clothing images and deduce the logical washing machine parameters.
- **Pillow (PIL)**: An image processing library used to handle the picture files before sending them to the AI.
- **JSON & Pydantic**: Crucial data structuring libraries used to strictly validate that the AI returns exact formatting (e.g., ensuring "temperature" is a number, not a text string).

---

3. Stage 1: API 1 - Clothing Material Identifier

Purpose and Functionality

The first stage of our pipeline serves as the sensory input, or the "Eyes," for the washing machine. Users upload up to five images of clothing items simultaneously. The API processes these images using the Gemini vision model to confidently identify three key pieces of information: the specific fabric name (e.g., Denim, Chiffon), the fiber category (Natural or Synthetic), and the dirt level on a scale from 1 to 5.

By extracting this data accurately, the machine knows exactly what it is preparing to wash before a single drop of water is dispensed.

User Feedback Loop (Self-Learning)

We implemented a self-learning mechanics system within API 1. If the AI happens to misidentify a fabric, users can submit a correction to a special feedback endpoint. This correction is securely stored, and the system can perform a retry where the previous incorrect prediction is explicitly fed back into the AI prompt (e.g., `"IMPORTANT: 'Cotton' was INCORRECT! Look more carefully..."`), forcing the AI to self-correct and provide a highly accurate answer.

Important Note on Implementation Safety

> ***IMPORTANT:*** *To prevent the AI service from crashing due to sudden bursts of requests, rate-limiting and automatic model failovers were strictly implemented. If the primary* `gemini-1.5-flash` *model gets overwhelmed, the system gracefully waits or automatically switches to a backup AI model.*

Code Snippet: Vision Processing Logic

The following backend code snippet demonstrates exactly how we instruct the AI to process the image and extract the required fabric details:

```python
async def predict_material(image_bytes: bytes, previous_error: str = None) -> str:
    # We initialize the smart vision model
    model = genai.GenerativeModel('gemini-flash-latest')
    image = Image.open(io.BytesIO(image_bytes))

    # Strict instruction prompt sent to the AI
    base_prompt = """Objective: Look at this photo of clothing.
    1. Tell me the specific fabric name (like Cotton or Silk).
    2. Tell me if it's Natural or Synthetic.
    3. Tell me how dirty it is on a scale of 1 to 5.
    Return the answer in a strict JSON format."""

    # We send the picture and instructions to the AI, and capture its JSON reply
    response = model.generate_content([base_prompt, image])
    return response.text.strip()
```

---

4. Stage 2: API 2 - Washing Parameter Predictor

Purpose and Functionality

Once the materials are identified, that data is transmitted to the second stage of our pipeline. This API acts as the "Brain" of the washing machine, translating the fabric descriptions into mechanical instructions readable by the hardware.

A significant engineering challenge was processing mixed loads. If a user uploads a delicate silk shirt alongside heavily soiled denim jeans, washing them the same way would ruin the silk. To solve this, we developed a custom **Concentration-Based Load Scaling** algorithm.

The Load Scaling Algorithm Rules

The algorithm safely combines settings for different clothes using the following logic:

- **Temperature Safety**: The brain reviews all items in the batch and selects the lowest, safest temperature across all garments so no delicate items shrink.
- **Spin Time**: It calculates the lowest spin time to prevent stretching delicate fabrics.
- **Water Volume Rules**: It precisely calculates water dynamically based on load size but hard-caps the limit at 60 Liters to completely prevent hardware flooding or overflowing.

Handling Edge Cases

A major part of building this system was ensuring it doesn't fail under strange conditions. For example:

- **What if someone uploads a picture of a dog?** API 1 will fail to identify a fabric and will throw an error, preventing API 2 from running a wash cycle for a pet.
- **What if the user uploads 5 completely different fabrics?** Because our algorithm strictly selects the *minimum* safe temperature and the *gentlest* mechanical action required by the most sensitive item in the batch, a silk shirt washed with dirty denim might not get the denim perfectly clean, but it guarantees the silk shirt is not destroyed. **Equipment and clothing safety is the highest priority of the system's algorithm.**

Code Snippet: The Merging Algorithm

The following mathematical code snippet calculates the absolute safest settings for mixed loads:

```
def combine_washing_params(logics):
    # Protect delicate clothes by identifying the safest minimum temperature
    safe_temperature = min(item.temperature_setting for item in logics)

    # Protect delicate clothes by identifying the lowest safe spin time
    safe_spin_time = min(item.spin_time for item in logics)

    # Calculate enough water for the clothes, capped strictly at 60 Liters
    calculated_water = calculate_water_based_on_items(logics)
    water_amount = min(calculated_water, 60)

    # Return the final, combined safe instructions
    return DressingLogic(
        temperature_setting=safe_temperature,
        spin_time=safe_spin_time,
        water_level=water_amount,
        mechanical_action=gentlest_action,
    )
```

---

5. System Integration and Proof of Execution

To validate that both the "Eyes" and "Brain" APIs function harmoniously, an automated pipeline test script was developed. The script injects a test image of dirty denim into API 1, validates the data upon return, and seamlessly routes that data into API 2 to output the final machine settings.

Execution Log Output (Terminal Screenshot Equivalent)

Below is the exact output generated by the system terminal during a successful end-to-end run. This serves as a text-based screenshot proving the workflow is fully operational from A to Z.

```

7. Conclusion

Throughout this project, we successfully engineered a sophisticated algorithmic bridge between visual intelligence and mechanical reality. By strictly segregating visual classification responsibilities (API 1) from physics and parameter derivation logic (API 2), we built an intelligent suite perfectly suited for smart home appliance integration. We completely eliminated the need for human guesswork in the laundry process.
